Abstract. In this paper we will address the questions of what and where the value of open access to research data might be and how libraries and related stakeholders can contribute to achieve the benefits of freely sharing data. In particular, the emphasis is on how libraries need to acquire the competence for collaboration to train and encourage researchers and library staff to work with open data. The paper is based on the early results of the RECODE project, an EU FP7 project that addresses the drivers and barriers in developing open access to research data in Europe (<http://www.recodeproject.eu>).

Keywords: Open data, libraries, Open Access

1. Introduction

During the last 30 years libraries have responded to new demands while analogue media turned digital. Librarians have creatively adapted to passing fads, and/or long lived realities such as Archie, Gopher, NCSA Mosaic, FTP, SGML, XLM, Open Access, PDA etc. Today most university libraries have institutional repositories and a digital publishing department dedicated to supporting researchers' needs of dissemination, preservation and open access advice. Libraries have long experience with advocacy, training and implementation of open access of publications and of dealing with digital information but now, when we are finally talking about a tipping point for scholarly open access documents [1], a new hot topic with a whole new set of demands on library skills, budgets and organization have arrived – open data.¹

Open Access (OA) to research data is increasingly regarded as a positive development that should be encouraged and stimulated within the European research landscape. The European Commission is pushing for research data to be more open in its Framework Programme Horizon 2020 [17], and the trend is also growing within the individual member states as well as the academic community. Several influential journals are now encouraging or requiring researchers to make the data that supports their publications freely accessible (for example all the BioMed Central journals, The Open Access Geoscience Data Journal, Dataset Papers in Science, eLIFE, F1000Research etc.) while several national and private funding agencies list open access to research data as a condition for funding. However, achieving open access

¹By “open data” we refer to research data defined as any material, used as a foundation for research.

and realizing its benefits requires considerable work, as the growing literature on data sharing and open access shows.

There now seems to be a more general consensus about the value that open data can bring to science and society. According to its advocates, unrestricted and digitally facilitated access to data would enable faster progress in science through minimising duplication of effort and offering scientists a wider range of data to use for re-analysis, comparison, integration and testing. It would contribute to the quality and integrity of scientific practices, as it increases transparency and accountability. It would also improve the way science and scientific data can be used in relation to social goals, and thus enhance the value of the contribution that science makes to society. Moreover, there is a strong notion that open data will be beneficial to innovation and economic growth. The European Commission, for example, refers to open data as “an engine for innovation, growth and transparent governance” [7].

Within these developments libraries are currently giving shape to their new role in facilitating open access to research data. In their Roadmap for Research Data the League of European Research Universities listed the library as a main source for data management and discovery [11]. Yet open access and the re-use of research data have proven to be a challenge in most disciplines. Many repositories, created to encourage data sharing, remain largely empty [15].

The central question posed in this paper is: how can libraries handle this new service together with other open data stakeholders in the academic world? The paper presents a review of policy documents, reports, scholarly literature and other relevant documents to provide an overview of current developments within the field. Despite the difficulties a few vanguard libraries have felt a need to support researchers in the management and dissemination of research data. In this paper, we will take a closer look at some of these initiatives, which often started as ‘new opportunities’ projects aiming to expand library services in a time where classic university library activities like cataloguing, media acquisition, subscription services etc. are questioned or being replaced or automated. We provide an analysis of some of these approaches in order to identify good practices and potential barriers.² We focus in particular on five aspects of the new role of libraries that is currently being shaped in these new approaches.

2. Training and advocacy

The first aspect of the role of libraries in open access to research data is providing support to researchers in managing their data and creating awareness about the possibilities of data sharing and open access. One reason why data sharing and open access is still not the norm in most disciplines is that researchers are reluctant to make their data public. Their concerns range from work being scooped or misused, to not having enough time or funding to make their data accessible, to maintaining the privacy and confidentiality of their research participants [15]. These concerns are often based on a lack of information about the possibilities in making research data open.

Another key problem is that it requires considerable technical skills to translate data in to machine-readable formats and to use the software tools to access and analyze the data. Researchers that wish to make their data publicly and digitally available and re-usable have to become acquainted with software tools and data formats that might not easily fit their existing research practices. Re-using data, in turn, requires researchers to learn about how to search and use data through web-based tools. It can also be

²This paper is based on findings made in the ongoing work packages of the RECODE project [16], funded by the European Union’s Seventh Framework Programme for research, technological development and demonstration under grant agreement no 285593.

difficult to find common standards and formats to share data, such that others can easily interpret and use the data. These practical barriers are also reflected in the European Commission's *Online survey on scientific information in the digital age* [8]. About 90% of the respondents in this survey disagreed with the statement: "Generally speaking, there is NO access problem to research data in Europe". Providing training to researchers and technical staff as well as creating awareness about the possibilities and limitations of data sharing will therefore be conducive to making more research data openly accessible in the various disciplines.

Academic institutions including libraries have an important role to play in training and advocacy. The Commission's survey also included the question how the European Union could best contribute to access and preservation of scientific publications and data. Most respondents agreed strongly with the statements "supporting the development of a European network of repositories" and "encouraging universities/research institutes, libraries and funding bodies etc. to implement specific action" [8]. Since many funding bodies already place responsibility for data management policies and compliance with research institutions, this increases the pressure on the academies to make data openly available. In the Opportunities for Data Exchange (ODE) project [5] it is spelled out: "Improving the skills and understanding of researchers in data management is essential. Training should begin in the institutions that train researchers, at the outset of postgraduate study and the latest, possibly even earlier". It is pointed out repeatedly that discipline-focused education in data management best practice must be incorporated into student and researcher training at an early stage [3,5,26]. So in order to play an active part in establishing open data libraries and to build competence for this, cooperation with other university stakeholders is important as well as being pro-active in open data management advocacy and training.

Nevertheless, within the whole academic community there is a lack of professional preparation for data management and no one is really taking responsibility for the research data management function. In many ways libraries are in a good position to take on this responsibility but the standard curriculum of library schools do not prepare students for managing data. This has to change. Preparing data management plans and training staff to accomplish them is new and mostly uncharted waters for universities and research institutions but there are some good examples of and reports on how to support these institutions in open data management [18,21,22,27].

3. Different cultures and target groups

A second aspect of the new role of libraries is dealing with the many different interests and requirements of the various disciplines and fields. In the material reviewed it is a common observation that researchers are a very heterogeneous group. Not only discipline-wise but also between individuals within the same team. Therefore it is important to gain an understanding of the "culture" within any given set of researchers before considering how to influence their research data management behaviour [24].

Research data is different from publications. It is more diverse and often linked to project communities, which calls for new ways of working, thinking and cooperating for librarians. Data diversity, tools and researcher needs should not be measured at the disciplinary level but at the research group level. In the literature review we have come across several recommendations that stress that for advocacy and training purposes interviews, case studies and surveys should be developed to understand researcher requirements and behaviour [3,9,13,22,27]. This must be the basis for developing advocacy/training materials that will motivate researchers, as well as making them understand the obligations to institutions, funders and the public.

Preparing data management plans and training staff to accomplish them is new and mostly uncharted waters for universities and research institutions but there are some good examples of and reports on how to support these institutions in open data management. The University of Southampton provides such an example. Mark L. Brown and Wendy White tell the story of how this university through collaboration with UK Research Data Service and involvement in projects like the Institutional Data Management Blueprint Project (IDMB) started to improve and formalize initiatives to support researchers at the university in managing their research data [18]. For training purposes, the use of automated- and web tools was set up. For example automated tools to support minting of DataCite DOIs and web based guidance to help interpret funders' requirements. For data management planning service for researchers a training program was developed to engage with various groups from postgraduate researchers to senior scientists. Planning and realization of these courses, lectures, workshops and seminars were always done together with the researchers themselves. The University of Southampton is one of many examples of how initiatives for data curation projects do not stop with collaboration inside the university departments. Many times necessary skills are only available through partnering with outside institutions or organizations [19,27].

In a consultancy report made for Jisc [12], the roles, rights, responsibilities and relationships of institutions, data centers and other stakeholders who work with data were explored. The conclusions regarding advocacy and training are very similar to the conclusions from Southampton: The importance to target and tailor measures to specific disciplines and sub-disciplines; awareness of data curation and preservation good practice is generally low but it varies a lot between disciplines; recommending data center and institutional repository staff to go out and promote their training programs with a mix of methods, seminars, workshops, lessons etc.

4. Bottom up or top down?

A third aspect to consider for libraries in giving shape to their data management support role is how to balance a policy level push for open access with servicing bottom-up initiatives from researchers themselves. On the one hand bottom-up approaches can take a long time to spread throughout research ecosystems. The typical United States data curation program is "devoid of top-level mandates and incentives, but rich with independent 'bottom-up' action". A structure like this is based on enterprising individuals and makes for a slow speed of development [27].

On the other hand, the reason libraries have started data curation programmes at all is due to their vanguard position relating to open access publications repositories and the digital preservation initiatives early explored by university libraries. This is also said to give the library opportunity to leverage existing partnerships and engage in new ones to build skills and necessary alliances for data curation [9,23]. Engaging with a few research communities as a start up pilot is a way to gain acceptance, formalization and getting program commitments from administrative levels. A successful project might well be a way of convincing university administrators of the benefits of a university wide curation policy and mandate [27].

In a recent American survey with the aim to identify current trends in research data management at research institutions only 9% of the respondents answered yes to the question "Does your institution have a Data Management (DM) policy"? Close to 90% agreed with the follow up statement "An institution-wide DM policy is important" which shows that university stakeholders like researchers, librarians, office of research staff, teachers etc. are keen to see such policies implemented [19].

In Southampton [18] the response to the insight that funders increasingly placed responsibility for data management policies and compliance with research institutions resulted in a bottom-up approach based on researchers needs and an incentive to design requirements for an institutional top-down approach policy and infrastructure. Their experience with open access publishing repositories was that “researchers were open to new practice as long as it was researcher led, integrated into research workflow, reflective of discipline distinctions and supported by advice and training. Clarity over policy and responsive service support were essential”. At the same time, it was very important that the institutions at the university felt that they were in command of the investments and service support regarding data management without feeling compelled by a set of requirements. Of the key components presented here – an institutional policy framework, a working institutional data registry, a one stop shop for data management advice and guidance and a sustainable business model it is the university policy on research data management that is considered the most important.

In the end a formal mandate is needed. Librarians introduce and administer the institutional repository and the idea about open access with a great knowledge about scholarly communication issues but since they do not bring any funding into the university the library is mostly perceived as a service based unit without much influence. Because of this power balance there is a need for a formal mandate or policy from a higher university authority [12].

But in the meantime, and as a first step to a formal policy, when there is no clear guidance from government authorities and university administrations are withholding resources or initiatives on data management issues, the bottom up approach is a way to start where advocacy is the first step only.

5. New partners

Working with other stakeholders is a fourth important aspect of the new role of libraries. The barriers to open research data are many and it is not realistic to believe that one stakeholder can solve all the challenges single-handed. There is a strong need for cooperation inside as well as between organisations, sharing expertise and specialist knowledge. In the current, very highly, competitive university climate, productivity and quality are buzzwords, and increasingly funding for research is based on bibliometrics. In this environment it is becoming more important for university management to keep track of the productivity and quality of the research publications. At the same time more funders are mandating open access and universities are struggling to promote their brand in order to hire the best scientists and attract the brightest students. In this landscape many librarians realize that their services, including repositories, is one of many that have to interconnect in order to support and make research more visible.

Today, university libraries are investigating possibilities of integrating institutional repositories with CRIS systems (Current Research Information System) usually run by university research offices or similar departments [10]. In Sweden this is being investigated on a national level where the national repository portal SwePub will possibly be integrated with the Swedish Research Councils CRIS system [25]. Universities like the University of Edinburgh have integrated all research service into one department (Information Services) which include classical library functions but also have divisions like IT-infrastructures, Digital Curation Center, the Jisc-designated national data centre EDINA and the Data Library [21].

It is evident that an important new role for the library going down the e-Science road is to be a competent team player when it comes to build such support structures for researchers. This is best done together with other important players at the university – Research Office Services, Archive staff and Academic IT Services and of course data centre specialists.

No matter how libraries approach the challenge of data curation, an introduction of new skills in the library profession is sorely needed. Working in partnership with scientists, future job roles as “data librarians” must contain skills both on the technical side and the archival side of the data coin. Specialists like this will play a key role in the scholarly publication process and must be rewarded accordingly. Library schools need to introduce courses that fit these new job descriptions. There is a need for convergence between library and archival skills in order to make university repositories a well functioning place for open data. This could also be a part of professional development and training [12]. This is also true for library professionals vis-à-vis research office professionals who are close to researchers supporting them with project applications, statistics etc. There might also be a chance for classic library roles such as liaison librarians to expand. Liaisons can help researchers depositing their data at the point of data creation. They can advice about standards, create curation plans for the whole life cycle of the research data in full compliance with funder mandates [9].

Collaborations between libraries and data centres and archives can also be beneficial in the area of training and skill development. As stated earlier, the skill levels of researchers regarding data management are variable and training is much needed. So parallel to advocacy there is a requirement for development of community skills. Since most of the expertise in data management is concentrated in data centres, progress can be made in this area from engaging and formalizing a flow of knowledge from data centres to institutions. Since 1976, CESSDA (Consortium of European social science data archives) has served as an informal umbrella organisation for the European national data archives. The CESSDA data archives and other similar subject data archives are in a good position to work with universities libraries and negotiate with archives on training.

Sometimes there is a polarization of views regarding the role of institutional repositories for data. Data centres and data archives have a more long-term perspective than the institutional repositories, which are relatively new structures yet to prove their ability. But both data centres and libraries have a stewardship role in data curation activities. They both help and guide researchers depositing their data. Dividing the different roles on short-term, easily accessible storage taken care of by institutional repositories and long-term preservation by data centres could be one way to facilitate for better data management support and cooperation [12].

6. Funding

Finally, an underlying issue of the new role for the libraries in open data management is of course the question about funding the new services. There is obviously a need for the university to make financial plans for the costs of storage, curation, training etc. for research data. Nevertheless, it can be a major problem to convince university administrations to gather resources for developing data curation models. In fact, most of the scarce funding for research data management is coming from libraries themselves [19]. Usually there is no extra seed money available inside the organization and libraries either have to reallocate internal resources or find external funding, for example by cooperating with outside partners. Therefore the initiation of grants and funding for libraries on national or international levels will be an important factor for getting data curation to gain speed on a broader level at universities [27].

There will probably be no real increase in funding without institutional or national mandates implementing research data management plans. Bottom-up practices are slow generators of change and general acceptance and will therefore have to be complemented with formal policies.

7. Conclusions and discussion

Among the major academic stakeholders in the open data ecosystem we have the funders of science – the councils and foundations; the creators of data – the researchers and we have the disseminators and curators of data – in this case the libraries, archives and the data centres. All these stakeholders with their organizations will need to cooperate. The barriers are multiple and complex and only joint forces can realize the idea of open data. Funders and policy makers need to clearly mandate data management and also earmark funds for training, infrastructure, data curation projects etc. Professional associations have to reflect on instigating new opportunities for training of professionals. Librarians, IT-specialists and research office staff from the universities need to collaborate with archivists and curators from data centres and vice versa. Researchers need to find new priorities regarding the importance of data management and ways to make data management pay career wise.

All this cooperation is already going on but it will have to spread and it has to be fuelled by governmental and academic authorities that issues policies that can facilitate cooperation and clear roadmaps for the way forward. Equally important are the non-governmental advocacy groups and other cross-professional organizations that have taken an interest in pushing the question of open data forward. Organizations like COAR, EUDAT, LIBER [4], RDA, SHERPA, SPARC, KE and many more are doing a fantastic job of advocating and informing about the importance of open data management and they are a important resource for libraries that are about to start data curation schemes.

There is a current gap of technical knowledge and access to proper infrastructure but there is also among the libraries and librarians a lack of understanding of the complexity of the process of managing open data. Based on the research performed in the RECODE project so far, we argue that the value of unrestricted access to research data depends significantly on the quality of the OA process. Our analysis of the values and motivations amongst researchers regarding OA showed that approaches to support and improve the development of open access to research data need to address at least the following issues:

- They should be sensitive to the different scientific practices to ensure that existing research rigour is maintained as well as facilitating OA.
- They should make the link between infrastructures, legal and ethical issues, and institutional frameworks, so that the OA ecosystem can support an appropriate approach to all types of data within their research areas.
- They need to provide safeguards for anonymity and privacy of research participants.
- They should provide ways to reference and attribute all open data correctly as part of ethical research practice.
- They need to pay attention to technological issues; such as the way technology drives the collection of vast datasets, the lack of technical infrastructure to store data and interoperability issues.
- Cultural barriers are significant, especially issues such as competition within science for reward and reputation, the lack of trust between scientists and the lack of career related rewards and prestige resulting from publishing and sharing data.

It is vital for libraries to realize that now is the time to be proactive regarding research data management – introducing professional preparation programs, starting up pilot programs, monitoring major data initiatives like DataCite, DataONE etc. and good examples of library initiatives like University of Edinburgh [21], University of York [20], University of Southampton [18], Max Planck digital library [14] or Purdue distributed data curation center [6] or else risk being bypassed by other players in the arena of establishing research data management programs.

The role of libraries in data management training is not evident for everyone. Some researchers agree that libraries should have an increasingly important role as data managers and experts based on their role in open access article publishing. Others argue that data centres could provide the support needed to handle the data correctly [5]. It is high time to reflect on these issues and to start studying experiences made so far in the urgent task of making research data openly available. If the library does not see the potential in the task of pioneering open research data, as it has in advocating open access to research publications, there is a major risk that other stakeholders quickly will fill that role and expand services vis-à-vis researchers, and librarians will be left with the question of how libraries can engage in making data open unanswered.
