

Introduction

We are pleased to present another issue of *NeuroRehabilitation*, focusing on a wide variety of topics. Subjects especially relevant to clinical practice are discussed. Within this issue, DeHope and Finegan report on the use of the “Self-Determination Model” to assist individuals with neurologic deficits to improve their self-awareness. Parente and Stapleton present their research on the effectiveness of a group-centered cognitive skills training model for vocational rehabilitation. In a case study by Hogan, narrative therapy is offered as a useful tool for rehabilitation following brain injury. Kolakowsky-Hayner and Kishore describe caregiver functioning and psychological distress in care-

givers of individuals with traumatic brain injury versus traumatic spinal cord injury. A pilot study is presented by Taskinen on the development of a health enhancing exercise group for patients with hemiplegia. The issue is completed with a review article on ethics in the field of medicolegal evaluation of neurologic injury by Martelli and colleagues.

As always we appreciate the contributions of professionals in the field. We are confident you will find the information contained in this issue to be both enlightening and practical.
